Prove It, or Get Out.

The AI-safety field keeps rediscovering the same wall. No model can be faithful, calibrated, and covering at once. No prompt-injection defense can be both complete and utility-preserving. No probe reads truth off a network exactly. These look like three separate frustrations. They are the same impossibility, wearing three masks.

This book traces all of them to one theorem, Lawvere's 1969 diagonal fixed point, the root of Cantor, Gödel, Tarski, and Turing, plus the intermediate value theorem. Three impossibilities, one argument, no fourth escape. And every proof is machine-checked in Lean 4. Sorry-free.

It stays honest about its reach: the mathematics has been settled since 1969; the force rests on the modeling premises; it proves these limits *exist*, not how often you will meet one.

Read the liar query. Find the diagonal.

Pick two. The third is a fixed point.

Made in the spirit of the hacker zines; not affiliated with or endorsed by any of them. The full text is free as a PDF, if you bought this, you bought the artifact.
